

AeroOps — Executive Summary

The Operating System for Aviation

AeroOps is the system of record a flight operation runs its entire day on — scheduling, dispatch, maintenance, training, and money as one continuous, auditable motion. It is what airlines have had for decades, at a price and polish a six-aircraft flight school can adopt in an afternoon.

Who it's for. Part 61 and Part 141 flight schools, flying clubs, rental operators, university aviation programs, and corporate flight departments — the owner-operator who is also the operations department, and the multi-role team that grows around them.

The problem. Small aviation runs on whiteboards, dispatch binders, and a patchwork of single-purpose tools that don't share data. The schedule doesn't know the airplane is grounded; the invoice doesn't know the flight closed; checkride readiness lives in the chief instructor's head. The incumbents digitized the *forms* — not the *operation*.

What ships today

- **Scheduling** — conflict-aware booking of aircraft, instructors, and students.
- **Dispatch** — release, then Hobbs/Tach closeout that updates meters, ledger, and invoice in **one atomic transaction**.
- **Maintenance** — squawks, work orders, signed return-to-service, auditable parts movement, fleet health.
- **Training** — students, instructors, endorsements, stage checks, and checkride readiness on the record.
- **Billing** — invoices, payments, and receivables built into the operation.
- **Reports & Executive view** — utilization, revenue, and productivity you can defend.
- **Mission Control** — a live, full-screen operations wall with an audit timeline.
- **Role-based dashboards + RBAC + immutable audit trail** across every seat.
- **Import Center** — map, test (a real rolled-back run), commit, and roll back, with presets for Flight Circle, Flight Schedule Pro, FlightLogger, and more.
- **Multi-tenant SaaS** with self-serve onboarding, a public API, an installable mobile PWA, and explainable AI insights that advise but never act.

Roadmap (clearly future): email/SMS delivery, Stripe payments, live METAR, cloud document storage, native mobile apps, and predictive operational intelligence. These plug into seams already built.

Why it's different

- **One operating system, not five point tools** — a single data model, not a scheduler with add-ons.
 - **Atomic dispatch → invoice** — a closed flight cannot silently go unbilled; revenue leakage is structurally impossible.
 - **Explainable by construction** — every conflict, readiness score, and insight carries its reasons; the audit trail is a first-class surface.
 - **Role-based** — the student, CFI, dispatcher, chief instructor, ops director, and owner each open their own AeroOps, personalized by permission.
 - **Import with rollback** — switching costs, not features, are the real competitor; "test it, and roll it back if it scares you" removes the fear.
-

Run the operation, not the paperwork. Request a demo — aerops.io
